GraphDB Web App

Clemens Lee, Chris Martin, Taylor Ellis

Project Overview

Using the graph database Neo4j alongside APEX and a RESTful service (written in PHP), we implemented a service to allow users to view and share free events with other users.

url: https://apex.oracle.com/pls/apex/f?p=77063:1

Specifications

- Based on a user's liked categories, events will be recommended to them that contain those tags
- Users -
 - can follow other users, and see events those users are planning to attend
 - can create new events, which will be visible to all other users
 - have a dynamically created dashboard that is populated with data from the database
 - can search within the application for users and events, and view the pages for them

Graph database -- Neo4j

- Graph database everything represented as node or link between nodes
- Ability to better represent the complex relationships between nodes.

Database Comparison

Graph - Neo4j

- Relationships are built into the database, same quality as nodes
- Data remains represented in real-world style
- Node labels
- Single Node
- Node Properties
- Queries using Cypher

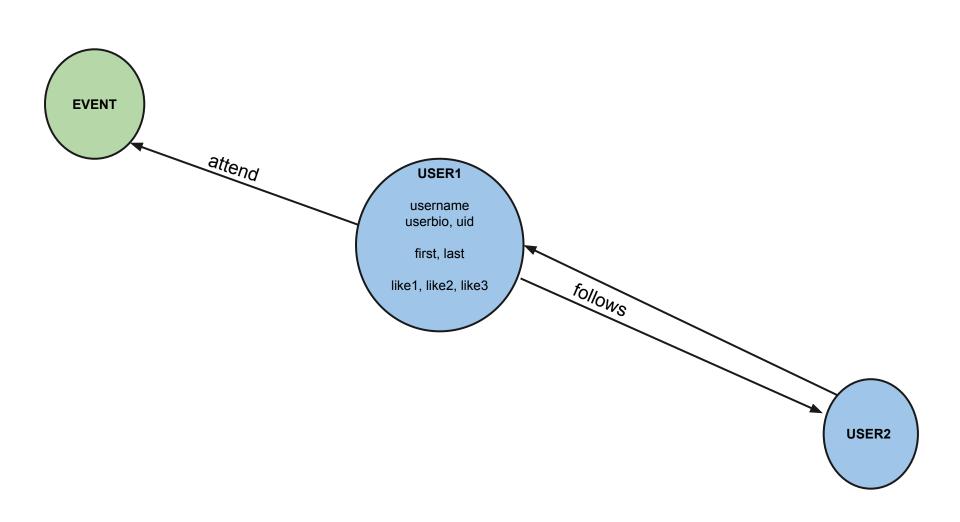

Relational - Oracle

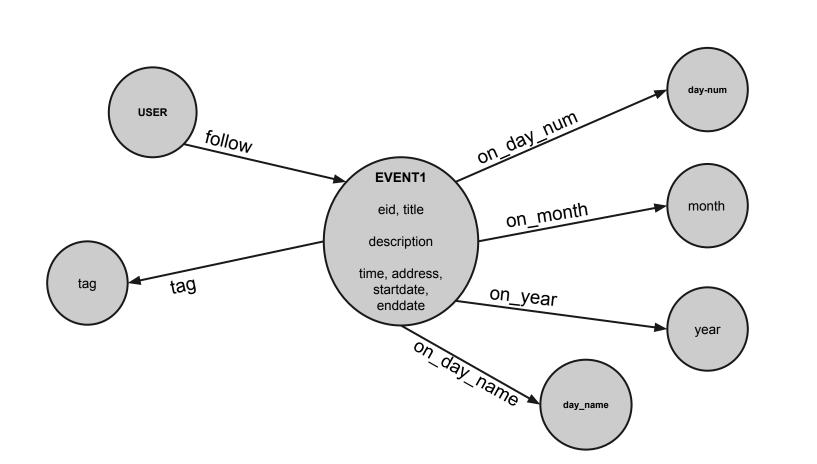

- Implied relationships (through foreign keys, etc.)
- Data has to be abstracted to a large degree
- Entity Table
- Row in the Table
- Column in the Table
- Queries using SQL

Neo4j Specifics

- Neo4j
 - node-property database
 - edges AND nodes can have properties

- Most Other Graph DBs
 - RDF database
 - only nodes have properties, edges are just connections

Cypher Example

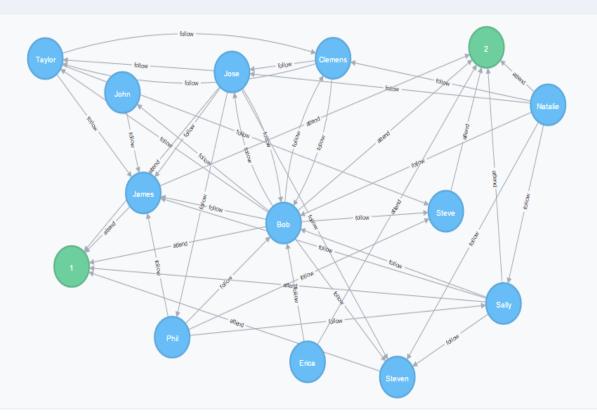

```
match (n {username: "pcannata"})-[]->(m)
set n.last = "Cannata"
return n, m
```

This query finds the node with the username "pcannata," sets the *last* property of that node to "Cannata", then returns that node, as well as all edges and nodes directly connected to it.

event(2) user(12)

attend(11) follow(32)

RESTful Service Intro

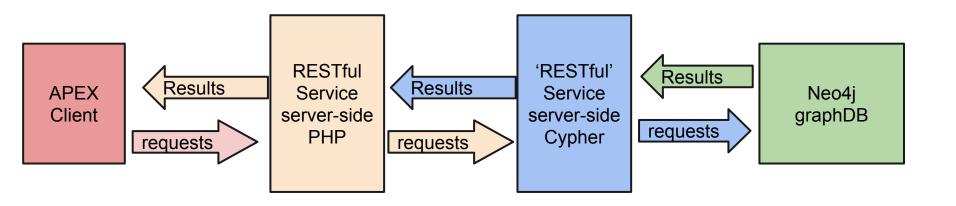

Representational State Transfer

- software architecture style to allow for scalable, distributed, maintainable web system
- GET, POST, PUT, DELETE, etc...
- web browser communication with server

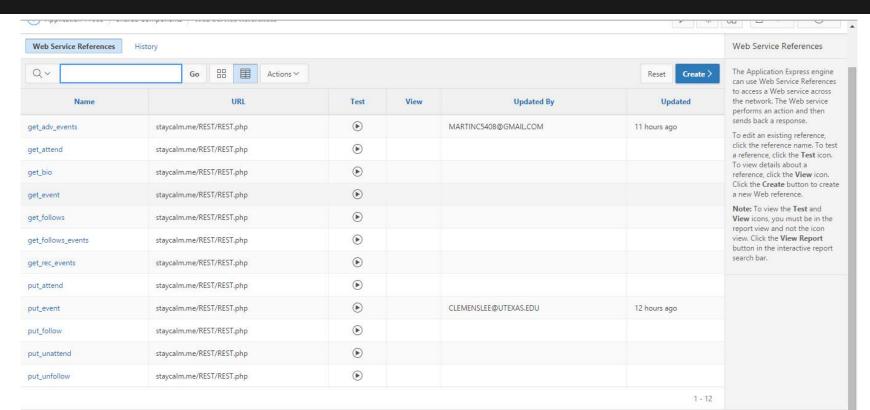

Our RESTful Service

- PHP RESTful service built on top of Neo4j 'RESTful'
 - cleaner calls from APEX
 - cleaner results
 - conform to RESTful guidelines

RESTful Communication

Web Services Shared Components

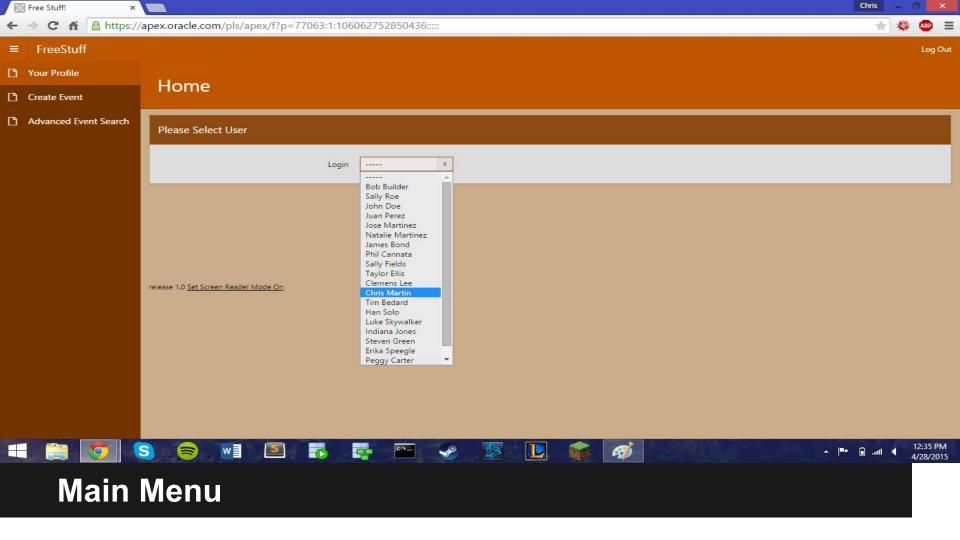

Web Service Processes

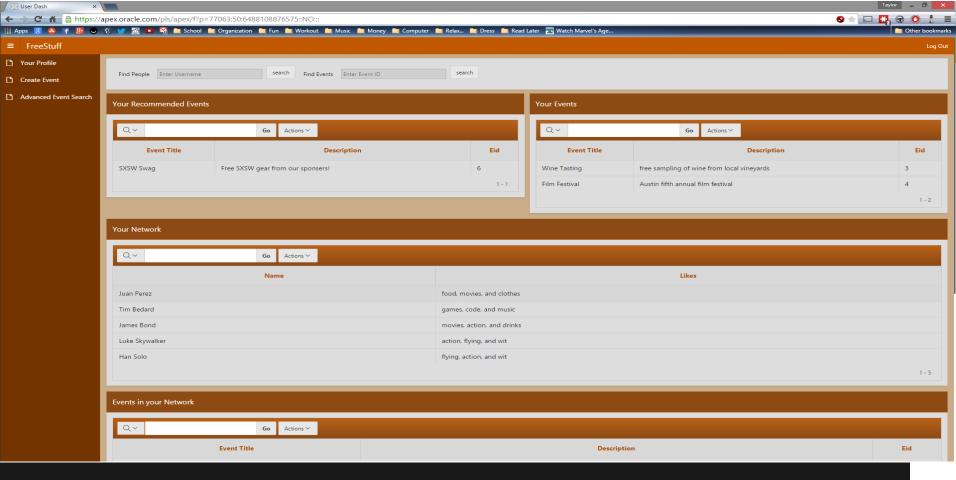

Web Service Processes

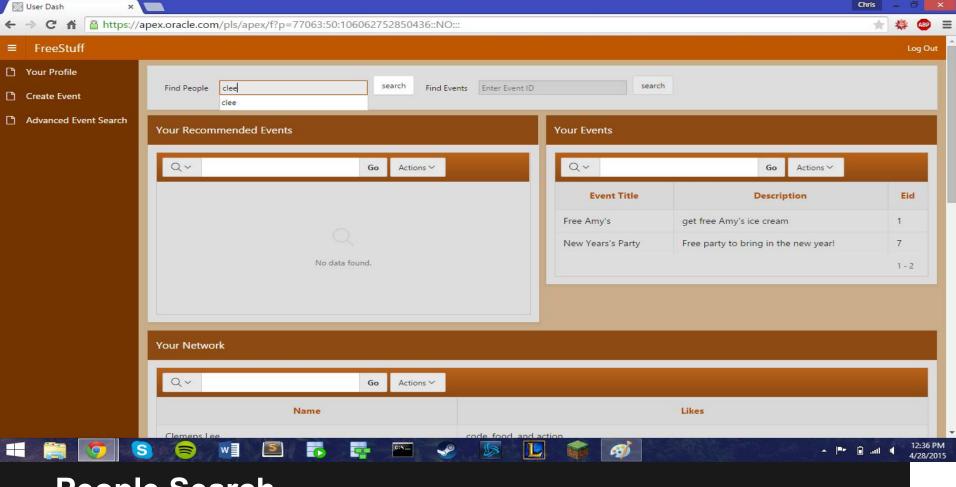

```
select title as "Event Title", description, eid
from xmltable (
     '/json/row'
     passing apex ison.to xmltype((select clob001 from apex collections
where collection name = 'P50 DOREST RESULTS REC EVENTS'))
     columns
      title varchar(255) path '/row/title',
      description varchar(4000) path '/row/description',
      eid varchar(255) path '/row/eid');
```
